Single View Calibration

- Single View Calibration (SVC) is the process of estimating the intrinsic calibration parameters (i.e. interior orientation) of a camera using only one perspective image
- It is a fundamental problem that needs to be solved before any metric measurements can be made from an image
- It is a key ingredient for single view reconstruction (SVR), i.e. the task of creating 3D graphical models for scenes for which only a single image is available

SVR example

End

- In contrast to grid based calibration, SVC cannot rely on the knowledge of the 3D coordinates of certain points in a world reference frame; a self-calibration paradigm must be adopted
- SVC also cannot rely on geometric constraints that need multiple images to be computed (e.g., Kruppa equations, absolute quadric)
- SVC should rely on geometric properties of the imaged objects
- Those properties should be supplied via user interaction

- A pair of vanishing points corresponding to orthogonal directions provides one calibration constraint [Caprile and Torre 1990]
- Dual of the above: A pair of vanishing lines corresponding to orthogonal planes provides one calibration constraint
- A metric planar homography provides two calibration constraints [Liebowitz and Zisserman 1998]
- Multiple calibration constraints can be combined in a least squares manner [Liebowitz and Zisserman 1999]
- Calibration constraints can also arise from surfaces of revolution [Colombo et al 2005]

Summary

End

- The applicability of SVC methods depends on a minimum number of calibration constraints being available
- This boils down to certain geometric arrangements occurring in the imaged scene
- Such arrangements are not guaranteed to always be present, thus an insufficient number of constraints might be available
- Insufficient constraints force the use of approximate, simplified camera models
- This work concerns a method for refining an initial calibration estimate (possibly obtained using a simplified model) with the aid of a priori known metric measurements

Single View Geometry

- Camera calibration is specified by matrix \mathbf{K} having 5 DOFs:

$$\mathbf{K} = \begin{bmatrix} f_u & s & u_0 \\ 0 & f_v & v_0 \\ 0 & 0 & 1 \end{bmatrix},$$

where f_u, f_v are the focal length in horizontal/vertical pixels, (u_0, v_0) the image principal point and s relates to the image axes angle. Usually cameras are *natural*:

aspect ratio $r \equiv \frac{f_v}{f_u} = 1, s = 0$

- Calibration is performed with the aid of the *image of the absolute conic* (IAC)
- The IAC is the image of an imaginary conic that depends only on the intrinsic parameters and not on camera pose
- A point \mathbf{x} on the IAC satisfies $\mathbf{x}^T \boldsymbol{\omega} \mathbf{x} = 0$, where $\boldsymbol{\omega}$ is a symmetric matrix $\boldsymbol{\omega}$ defined as $\boldsymbol{\omega} = (\mathbf{K}\mathbf{K}^T)^{-1}$

Experimental Results

Summary

End

- Calibration through estimating the IAC is convenient since SVC constraints are linear in the elements of ω
- Given ω , \mathbf{K} can be computed from its Cholesky decomposition
- The *vanishing point* (VP) of a 3D line is the point onto which infinitely far line points are imaged
- ω allows certain direct 3D measurements on images
- The VPs of non-parallel coplanar 3D lines lie on the same *vanishing line*

- Let $S(\mathbf{a}, \mathbf{b})$ denote the scalar $\mathbf{a}^T \omega \mathbf{b}$ for vectors \mathbf{a} and \mathbf{b}

- If \mathbf{v}_1 and \mathbf{v}_2 are the vanishing points of two 3D lines, the acute angle θ between them can be computed from

$$\cos(\theta) = \frac{|S(\mathbf{v}_1, \mathbf{v}_2)|}{\sqrt{S(\mathbf{v}_1, \mathbf{v}_1) S(\mathbf{v}_2, \mathbf{v}_2)}}$$

- Using the law of sines, the length ratio of four non collinear points A, B, C and D equals

$$\frac{AB}{CD} = \sqrt{\frac{S(\mathbf{v}_{ab}, \mathbf{v}_{ab})}{S(\mathbf{v}_{cd}, \mathbf{v}_{cd})} \cdot \frac{S(\mathbf{v}_{ac}, \mathbf{v}_{ac}) S(\mathbf{v}_{bc}, \mathbf{v}_{bc}) - S(\mathbf{v}_{ac}, \mathbf{v}_{bc})^2}{S(\mathbf{v}_{ab}, \mathbf{v}_{ab}) S(\mathbf{v}_{ac}, \mathbf{v}_{ac}) - S(\mathbf{v}_{ab}, \mathbf{v}_{ac})^2} \cdot \frac{S(\mathbf{v}_{bd}, \mathbf{v}_{bd}) S(\mathbf{v}_{cd}, \mathbf{v}_{cd}) - S(\mathbf{v}_{bd}, \mathbf{v}_{cd})^2}{S(\mathbf{v}_{bc}, \mathbf{v}_{bc}) S(\mathbf{v}_{bd}, \mathbf{v}_{bd}) - S(\mathbf{v}_{bc}, \mathbf{v}_{bd})^2}},$$

where $\mathbf{v}_{ab}, \mathbf{v}_{ac}, \mathbf{v}_{bc}, \mathbf{v}_{bd},$ and \mathbf{v}_{cd} are the VPs of segments AB, AC, BC, BD and CD

Summary

End

- Known angles and length ratios impose high-order polynomial constraints on ω
- Such constraints are not usable for directly obtaining ω due to the problems associated with solving nonlinear polynomial equations
- Given an initial calibration estimate, known metric properties can be used for improving it. The idea is to refine the estimated ω in a nonlinear optimization framework so that metric measurements made with it are in close agreement with those a priori known

- $\alpha(\mathbf{s}_i, \mathbf{r}_i; \omega) - \cos(\phi_i)$: cosine difference error, $(\mathbf{s}_i, \mathbf{r}_i) \in A$
- $\alpha(\mathbf{s}_i, \mathbf{r}_i; \omega) - \alpha(\mathbf{p}_i, \mathbf{q}_i; \omega)$: cosine estimates difference error, $(\mathbf{s}_i, \mathbf{r}_i, \mathbf{p}_i, \mathbf{q}_i) \in E$
- $\rho(\mathbf{s}_i, \mathbf{r}_i; \omega) - \lambda_i$: length ratio difference error, $(\mathbf{s}_i, \mathbf{r}_i) \in R$
- A cumulative error term $\epsilon(A, E, R; \omega)$ is defined by summing the squares of all cosine & length difference errors:

$$\epsilon(A, E, R; \omega) = \sum_{(\mathbf{s}_i, \mathbf{r}_i) \in A} [\alpha(\mathbf{s}_i, \mathbf{r}_i; \omega) - \cos(\phi_i)]^2 +$$

$$\sum_{(\mathbf{s}_i, \mathbf{r}_i, \mathbf{p}_i, \mathbf{q}_i) \in E} [\alpha(\mathbf{s}_i, \mathbf{r}_i; \omega) - \alpha(\mathbf{p}_i, \mathbf{q}_i; \omega)]^2 +$$

$$\sum_{(\mathbf{s}_i, \mathbf{r}_i) \in R} [(\rho(\mathbf{s}_i, \mathbf{r}_i; \omega) - \lambda_i)]^2$$

Summary

End

- Not all line segments involved in the definition of $\epsilon(A, E, R; \omega)$ should be coplanar
- An arbitrary number of constraints can be accommodated
- The error term can be iteratively minimized over ω using a nonlinear least squares algorithm, e.g. Levenberg - Marquardt
- The starting point for the numerical minimization is the initial estimate of ω
- Details on the parametrization of ω are in the paper; 3 or 4 parameters suffice
